DOCUMENTATION

Purpose

Report has been made to help doctors to fast spot epilepsy symptom pattern in kids. Using pediatric autism/epilepsy genetic variant 2023 snowflake marketplace data.

BI Analyst: Linda Aluso

Data Source

Definitions

Gene Risk Score:

A single "danger rating" for a gene, calculated by totaling the severity of all its known variants. It is the **Sum** of all **Variant Severity Scores** for that specific gene. It helps a doctor instantly see which genes are the "heaviest hitters" across the entire dataset

Gene Variant Severity:

A numerical weight assigned to a mutation based on how likely it is to cause disease. We translate medical labels into numbers (e.g., **Pathogenic = 1.0, VUS = 0.3**). It allows us to mathematically "rank" mutations so the most dangerous ones rise to the top of the doctor's list.

Gene Phenotype Evidence:

A count of how many times a specific gene has been linked to a specific clinical symptom (phenotype). It is the **Total Count** of recorded cases linking a gene (like *SCN1A*) to a symptom (like *Seizures*). It provides the "strength of evidence." A high risk score tells you a gene is dangerous; a high phenotype count tells you exactly how that danger usually shows up in patients.

Version History

April 2026- This is the first version including the overview page and the report information page.
